

# THE RADICLE REGISTRY

VERSION 0.1

ABSTRACT. What follows is a semi-formal description of the semantics of the Radicle Registry.

## CONTENTS

1. Transactions	2
2. Accounts	2
2.1. Transferring value	2
3. Orgs	3
3.1. Registering	3
3.2. Unregistering	3
3.3. Registering members	4
3.4. Unregistering members	4
3.5. The Contract	4
3.6. The Fund	5
4. Projects	5
4.1. Registering	5
4.2. Unregistering	6
4.3. Creating a checkpoint	6
4.4. Setting a checkpoint	7
5. User Identity	7
5.1. Registering	7
5.2. Unregistering	8
5.3. Associating an external key	8
5.4. Revoking an external key	8

## 1. TRANSACTIONS

All transactions on the registry take the form  $\text{transaction}(arg_1, \dots, arg_n)_\sigma$ , where  $arg_1, \dots, arg_n$  are the *inputs* and  $\sigma$  is the EdDSA signature of the author of the transaction. Transactions always have an *author* and an *origin* (formally  $\alpha$ ), which is the author's account.

Transactions can be uniquely identified by their *hash*. The set of all *known* transactions is  $\mathcal{T}$  (the “ledger”), and the set of all known transaction hashes is  $\mathcal{T}_{\text{hash}}$ .

## 2. ACCOUNTS

An account  $A$  is a tuple:

$$A = \langle A_{\text{id}}, A_{\text{nonce}}, A_{\text{bal}} \rangle$$

## DEFINITION

- $A_{\text{id}}$  is the unique account identifier obtained by hashing the account owner's public key,
- $A_{\text{nonce}}$  is a number which starts at 0 and is incremented every time a transaction originates from this account.
- $A_{\text{bal}}$  is the account's balance in the smallest denomination, and  $A_{\text{bal}} \in \mathbb{N}_{\geq 0}$ .

The set of all accounts is  $\mathcal{A}$ . Accounts are never created or destroyed, rather, if they have never been used to transact, they have an initial state of:

$$A = \langle A_{\text{id}}, 0, 0 \rangle$$

Hence, for all valid account ids, there exists an account with that id. In other words,  $\forall a \in A_{\text{id}} (A \in \mathcal{A})$ .

Note that accounts can *never be removed*, since that would violate the invariant that nonces are only ever incremented, and removing an account is equivalent to setting  $A_{\text{nonce}}$  and  $A_{\text{bal}}$  to 0.

**2.1. Transferring value.** The act of transferring coins between two accounts:

$$\text{transfer}(A_{\text{id}}, v)_\sigma$$

which will transfer value from the transaction origin  $\alpha$  to account  $A$ .

## INPUTS

- $A_{\text{id}}$  is the account id of the *receiver* of the transfer,
- $v$  is the value or ‘balance’ to transfer from the origin to the receiver, in the smallest denomination.

## VALIDATION

- The transfer balance is positive, or  $v \geq 1$ ,
- The origin's balance minus any transaction fee is  $\geq v$ .

## OUTPUTS

- $v$  is debited from the origin and credited to  $A$ .

### 3. ORGS

An org is a logical grouping of people and projects with common governance and funds. An org  $O$  is a tuple:

$$O = \langle O_{\text{id}}, O_{\text{account}}, O_{\text{members}}, O_{\text{projs}}, O_{\text{contract}} \rangle$$

#### DEFINITION

- $O_{\text{id}}$  is the globally unique org identifier,
- $O_{\text{account}}$  is the org account or *fund*,
- $O_{\text{members}}$  is the set of registered org members,
- $O_{\text{projs}}$  is the set of registered projects under this org,
- $O_{\text{contract}}$  is the org contract, which governs permissions around the org, as well as its fund. It can be described as a function:

$$f : \mathcal{T} \rightarrow \{\top, \perp\}$$

where  $\mathcal{T}$  is any transaction  $t$  operating on an org, and  $\top$  signifies  $t$  is *authorized* to execute by the contract, while  $\perp$  means it is *unauthorized*. Note that a transaction can be verified and included in the transaction ledger  $\mathcal{T}$  yet still be unauthorized to run by the contract

#### 3.1. Registering.

$$\text{register-org}(O_{\text{id}}, O_{\text{contract}})_{\sigma}$$

##### INPUTS

- $O_{\text{id}}$  is the unique identifier being registered,
- $O_{\text{contract}}$  is the initial org contract that includes the initial permission set around the org.

##### VALIDATION

- $O_{\text{id}}$  must be unique, i.e. not currently in use, between 1 and 32 bytes long, and valid UTF-8.
- $\alpha_{\text{bal}} \geq \mathcal{D}_{\text{register-org}}$ .

##### OUTPUTS

- $O \in \mathcal{O}$ , where  $O = \langle O_{\text{id}}, O_{\text{account}}, \{\alpha_{\text{id}}\}, \emptyset, O_{\text{contract}} \rangle$
- $O_{\text{account}} \in \mathcal{A}$ ,
- $\alpha_{\text{bal}'} = \alpha_{\text{bal}} - \mathcal{D}_{\text{register-org}}$ .

#### 3.2. Unregistering.

$$\text{unregister-org}(O_{\text{id}})_{\sigma}$$

##### INPUTS

- $O_{\text{id}}$  is the identifier of the org being unregistered,

##### VALIDATION

- $O \in \mathcal{O}$ ,
- $O_{\text{members}} = \{\alpha_{\text{id}}\}$ , the transaction origin must be the only member,
- $O_{\text{projs}} = \emptyset$ , there must be no projects under the org,

##### OUTPUTS

- $O \notin \mathcal{O}$ ,

$$- \alpha_{bal'} = \alpha_{bal} + \mathcal{D}_{\text{register-org}} + O_{\text{account}_{bal}}.$$

### 3.3. Registering members.

$$\text{register-member}(O_{\text{id}}, A_{\text{id}})_{\sigma}$$

#### INPUTS

- $A_{\text{id}}$  is the account id being registered as a member,
- $O_{\text{id}}$  is the id of the org under which to register  $A$ ,

#### VALIDATION

- $O \in \mathcal{O}$ ,
- $A_{\text{id}}$  must not already be registered under  $O$ , or  $A_{\text{id}} \notin O_{\text{members}}$
- The transaction author is authorized to execute **register-member**,
- $\alpha_{bal} \geq \mathcal{D}_{\text{register-member}}$ .

#### OUTPUTS

- $A_{\text{id}} \in O_{\text{members}}$ ,
- $\alpha_{bal'} = \alpha_{bal} - \mathcal{D}_{\text{register-member}}$ .

### 3.4. Unregistering members.

$$\text{unregister-member}(O_{\text{id}}, A_{\text{id}})_{\sigma}$$

#### INPUTS

- $O_{\text{id}}$  is the id of the org under which the member is registered,
- $A_{\text{id}}$  is the account id of the member being unregistered,

#### VALIDATION

- $O \in \mathcal{O}$ ,
- $A_{\text{id}} \in O_{\text{members}}$ ,
- The transaction author is authorized to execute **unregister-member**.

#### OUTPUTS

- $A_{\text{id}} \notin O_{\text{members}}$ ,
- $\alpha_{bal'} = \alpha_{bal} + \mathcal{D}_{\text{register-member}}$ .

**3.5. The Contract.** Every org  $O$  in the registry has a contract denoted  $O_{\text{contract}}$ . The way this contract is invoked is through transactions that act on  $O$ . For example, the **fund** transaction (§3.6) which transfers value out of a org is always validated by the org contract before it is authorized to execute.

A contract is made of a set of *rules* that each handle a specific action relating to the org. In the **fund** example, the **fund rule** would be invoked to determine the outcome of the transaction.

Setting the org's contract is done with:

$$\text{set-contract}(O_{\text{id}}, c)_{\sigma}$$

#### INPUTS

- $O_{\text{id}}$  is the id of the org,
- $c$  is the new contract.

#### VALIDATION

- $O \in \mathcal{O}$ ,
- The transaction author is authorized to execute **set-contract**,

OUTPUTS

- $O_{\text{contract}} = c$

**3.6. The Fund.** Each org has an associated account  $O_{\text{account}}$  called the *fund*. To use that account to fund maintenance of projects, the **fund** transaction is used:

$$\text{fund}(O_{\text{id}}, A_{\text{id}}, v)_{\sigma}$$

INPUTS

- $O_{\text{id}}$  is the id of the org from which the transfer should be initiated,
- $A_{\text{id}}$  is the id of the account that should receive the transfer,
- $v$  is the value to transfer.

VALIDATION

- $O_{\text{account}_{\text{bal}}} - \mathcal{D}_{\text{register-org}} \geq v$ ,
- The transaction author is authorized to execute **fund**,

OUTPUTS

- $A_{\text{bal}'} = A_{\text{bal}} + v$
- $O_{\text{account}_{\text{bal}'}} = O_{\text{account}_{\text{bal}}} - v$

## 4. PROJECTS

A project  $P$  is a tuple:

$$P = \langle P_{\text{id}}, P_{\text{org}}, P_{\text{k}}, P_{\text{meta}} \rangle$$

DEFINITION

- $P_{\text{id}}$  is the unique project identifier within the context of an  $P_{\text{org}}$ ,
- $P_{\text{org}}$  is the org under which this project lives,
- $P_{\text{k}}$  is the current project *checkpoint* (See §4.3),
- $P_{\text{meta}}$  is opaque metadata to associate with  $P$ . For example, the RADICLE *project id*. Note that once defined, the metadata is immutable.

Projects are registered with the **register-project** transaction and unregistered with the **unregister-project** transaction. Projects always exist within the context of an org.

### 4.1. Registering.

$$\text{register-project}(P_{\text{org}}, P_{\text{id}}, P_{\text{k}}, P_{\text{meta}})_{\sigma}$$

INPUTS

- $P_{\text{id}}$  is the unique project id being requested,
- $P_{\text{org}}$  is the id of the org under which to register  $P$ ,
- $P_{\text{k}}$  is the id of the initial *checkpoint* associated with this project, formally  $k_0$ . This checkpoint must always remain in the project ancestry,
- $P_{\text{meta}}$  is associated project metadata.

VALIDATION

- $P_{\text{org}}$  identifies an existing org  $O$ ,
- $P_{\text{id}}$  is unique under  $O$ , between 1 and 32 bytes long, and valid UTF-8.
- $P_k$  represents an existing checkpoint,
- $P_{\text{meta}}$  is  $\leq 128$  bytes long,
- The transaction author is authorized to execute **register-project**,
- $\alpha_{\text{bal}} \geq \mathcal{D}_{\text{register-project}}$ .

## OUTPUTS

- $P \in O_{\text{projs}}$ , where  $O_{\text{id}} = P_{\text{org}}$ ,
- $\alpha_{\text{bal}'} = \alpha_{\text{bal}} - \mathcal{D}_{\text{register-project}}$ .

## 4.2. Unregistering.

$$\text{unregister-project}(P_{\text{org}}, P_{\text{id}})_{\sigma}$$

## INPUTS

- $P_{\text{id}}$  is the project id being unregistered,
- $P_{\text{org}}$  is the id of the org under which  $P$  lives,

## VALIDATION

- $P_{\text{org}}$  identifies an existing org  $O$ ,
- $P \in O_{\text{projs}}$ ,
- The transaction author is authorized to execute **unregister-project**.

## OUTPUTS

- $P \notin O_{\text{projs}}$ ,
- $\alpha_{\text{bal}'} = \alpha_{\text{bal}} + \mathcal{D}_{\text{register-project}}$ .

**4.3. Creating a checkpoint.** The act of anchoring a project’s state in the registry:

$$\text{checkpoint}(K_{\text{parent}}, K_{\text{hash}})_{\sigma}$$

Checkpoints within the scope of a single project form a chain going from the latest, or “current” checkpoint  $k_{n-1}$  to the first and original checkpoint  $k_0$ . Checkpoints are identified by their transaction hash, so  $k \in T_{\text{hash}}$ .

From the perspective of  $k_0$ , we can talk of a checkpoint *tree*, since due to their nature, they are able to represent branching. Hence, the original checkpoint  $k_0$  is also called the *root* checkpoint.

## INPUTS

- $K_{\text{parent}}$  is the *id* of the previous or ‘parent’ checkpoint,
- $K_{\text{hash}}$  is the new hash of the project state,

## VALIDATION

- $K_{\text{parent}}$  refers to an existing checkpoint in the registry, or is  $\emptyset$ .
- $K_{\text{hash}}$  is a valid hash that hasn’t been used in a parent checkpoint.

**4.4. Setting a checkpoint.** The act of updating the project to point to a new checkpoint:

$$\text{set-checkpoint}(P_{\text{org}}, P_{\text{id}}, k')_{\sigma}$$

which updates  $P_{\text{checkpoint}}$  from  $k$  to  $k'$ .

INPUTS

- $P_{\text{org}}$  is the id of the org  $O$  under which the project lives,
- $P_{\text{id}}$  is the id of the project being updated,
- $k'$  is the id of the checkpoint the project should be associated to.

VALIDATION

- $P_{\text{id}} \in O_{\text{projs}}$ , or  $P$  lives under  $O$ ,
- $k'$  is a checkpoint which has the original project checkpoint  $k_0$  in its ancestry,
- The transaction author is authorized to execute **set-checkpoint**.

OUTPUTS

- $P_k = k'$

Note that the semantics of this transaction allows for projects to revert to a previous checkpoint, or to adopt a “fork”, as long as the new checkpoint shares part of its ancestry with the previous checkpoint.

## 5. USER IDENTITY

Identity in the registry serves as a way for users to consolidate the various keys and external identities they use under a short, human-readable name.

A user  $U$  is a logical grouping of *identities*, or user identifiers under a single, unique identifier,  $U_{\text{id}}$ . The set of all users is  $\mathcal{U}$ .

$$U = \langle U_{\text{id}}, U_{\text{account}}, U_{\text{keys}} \rangle$$

DEFINITION

- $U_{\text{id}}$  is the globally unique human-readable identifier of the user,
- $U_{\text{account}}$  is the account id which owns this user identity,
- $U_{\text{keys}}$  is the set of off-registry public keys associated with this identity.

**5.1. Registering.** We register a new user identity and thus user

$$\text{register-identity}(U_{\text{id}})_{\sigma}$$

INPUTS

- $U_{\text{id}}$  is the globally unique user identifier being registered,

VALIDATION

- $U_{\text{id}}$  must be unique, i.e. not currently in use, between 1 and 32 bytes long, and valid UTF-8.
- $\alpha_{\text{bal}} \geq \mathcal{D}_{\text{register-identity}}$ .

OUTPUTS

- $U \in \mathcal{U}$ , where  $U = \langle U_{\text{id}}, \alpha_{\text{id}}, \emptyset \rangle$
- $\alpha_{\text{bal}'} = \alpha_{\text{bal}} - \mathcal{D}_{\text{register-identity}}$

**5.2. Unregistering.**

$$\text{unregister-identity}(U_{\text{id}})_\sigma$$

INPUTS

- $U_{\text{id}}$  is the identity being unregistered,

VALIDATION

- $U \in \mathcal{U}$ ,
- $\alpha$  must be the owner of this identity, in other words  $U_{\text{account}} \equiv \alpha_{\text{id}}$ ,

OUTPUTS

- $U \notin \mathcal{U}$ ,
- $\alpha_{\text{bal}'} = \alpha_{\text{bal}} + \mathcal{D}_{\text{register-identity}}$ .

**5.3. Associating an external key.** The act of associating an external public key to a registered user identity:

$$\text{associate-key}(U_{\text{id}}, k, \pi)_\sigma$$

INPUTS

- $U_{\text{id}}$  is the identity under which to associate the key,
- $k$  is the public portion of the key pair  $\langle k, S_k \rangle$  that is to be associated,
- $\pi$  is a proof or signature verifying that the transaction author owns  $k$ , defined as:

$$\pi = \text{encrypt}(\text{hash}(U_{\text{id}}), S_k)$$

where  $S_k$  is the secret key from which  $k$  was derived.

VALIDATION

- $k \notin U_{\text{keys}}$ ,
- $k$  is a valid 32 byte Ed25519 key,
- $\alpha_{\text{id}} \equiv U_{\text{account}}$ ,
- $\text{decrypt}(\pi, k) \equiv \text{hash}(U_{\text{id}})$

OUTPUTS

- $k \in U_{\text{keys}}$

**5.4. Revoking an external key.** When a public key associated with the **associate-key** transaction is lost or no longer used, the following transaction will ‘revoke’ the association:

$$\text{revoke-key}(U_{\text{id}}, k)_\sigma$$

INPUTS

- $U_{\text{id}}$  is the identity under which the key is currently associated,
- $k$  is the key being revoked,

VALIDATION

- $k \in U_{\text{keys}}$ ,
- $\alpha_{\text{id}} \equiv U_{\text{account}}$ ,

OUTPUTS

- $k \notin U_{\text{keys}}$
